Copying Conversions Friends

- Version 1: Dr. Ofir Pele
- Version 2: Dr. Erel Segal-Halevi

.

Copy Constructor *(folder 1)*

- Called whenever an object of type T is copied.
- Copy Constructor to class T gets as argument **const T&** *(Why?)*
- You should consider for each class whether it needs **deep copy** or **shallow copy**.

Rule of Three

- A rule of thumb:
  - When you need to make a deep copy of an object, you need to define all of these:
    1. Copy constructor
    2. Destructor
    3. Operator =
  - Or in other words:

    when you need one, you need all.

A skeleton for deep copy

```cpp
// Copy constructor
A (const A& other) : init {
    copy_other(other);
}

// Operator =
```

```cpp
// Destructor
~A() {
    clear();
}
```

```cpp
A& operator=(const A& other) {
    if (this!=&other) { // preventing problems in a=a
        clear(); init // or recycle
        copy_other(other);
    } return *this; } // allows a= b= c= …
```

IntBuffer example *(folder 2)*

Conversions of types is done in two cases:

1. Explicit casting (we'll learn more about it in next lessons)

2. When a function gets **X** type while it was expecting to get **Y** type, and there is a casting from **X** to **Y**:

      void foo(**Y y**)

      ...

      X x;

      foo(x); // a conversion from **X** to **Y** is done

Conversions danger: unexpected behavior

Buffer(size_t length) // ctor

…

void foo(const Buffer& v) // function

...

foo(3); // Equivalent to: foo(Buffer(3))
// Did the user really wanted this?

The Buffer and the size_t objects are not logically the same objects!

Conversion example (folder 4)

User defined conversion (folders 5,6)

```
class Fraction {

    ...

    // double --> Fraction conversion
    Fraction (const double& d) {

        ...

    }

    ...

    // Fraction --> double conversion
    operator double() const {

        ...

    }
```

Operators ++ -- postfix prefix (folder 7)

```
// Prefix: ++n
HNum& operator++() {
 code that adds one to this HNum
 return *this; // return ref to curr
}

// Postfix : n++
const HNum operator++(int) {
 Hnum cpy(*this); // calling copy ctor
 code that adds one to this HNum
 return cpy;
}
```

A flag that makes it postfix

Operator Suffix (folder 8)

Operator Comma (folder 9)

friend

friend functions

Friend function in a class:

- Not a method of the class
- Have access to the class's private and protected data members
- Defined inside the class scope

Used properly does not break encapsulation

friend functions example: Complex revisited

friend classes

- A class can allow other classes to access its private data members

- *QUESTION: Is the friendship link one-sided or two-sided? I.e:*

  - *Suppose class A is a friend of class B.*

  - *Does it mean that class B is a friend of A?*

friend classes - example

```
class IntTree {

    …
    friend class IntTreeIterator;

};

// TreeIterator can access Tree's data members
IntTreeIterator& IntTreeIterator::operator++() {

    …
    return *this;

}
```
